3.1.1 Average frequency ..... 6
3.1.2 Standard deviation ..... 11
3.1.3 Mean value and standard deviation ..... 15
3.2 Frequency area ..... 20
3.3 1-, 5-, 10-, 90-, 95-, 99-percentile of frequency ..... 25
3.4 Time outside different ranges ..... 38
3.4.1 Time outside $49.9-50.1 \mathrm{~Hz}$. ..... 38
3.4.2 Time outside 49.8-50.2 Hz ..... 50
3.4.3 Time outside $49.0-51.0 \mathrm{~Hz}$. ..... 54
3.5 Number of frequency deviations with different durations ..... 55
3.5.1 Deviations with a duration of $0-1 \mathrm{~s}, 1-5 \mathrm{~s}, 5-10 \mathrm{~s}, 10-20 \mathrm{~s}, 20-40 \mathrm{~s}, 40-60 \mathrm{~s}$ and $1-3 \mathrm{~min}$ ..... 56
3.5.2 Deviations with a duration of 1-3 $\mathrm{min}, 3-5 \mathrm{~min}, 5-10 \mathrm{~min}, 10-15 \mathrm{~min}$ and $>15 \mathrm{~min}$ ..... 67
3.6 Number of threshold crossings ..... 71
3.6.1 Number of $49.9-50.1 \mathrm{~Hz}$ crossings ..... 71
3.6.2 Number of $49.8-50.2 \mathrm{~Hz}$ crossings ..... 76
3.7 Length of frequency path ..... 77
3.8 Amount of frequency oscillation ..... 82
3.8.1 Methodology ..... 82
3.8.2 Amount of oscillation ..... 85
3.8.3 Influence of oscillation on frequency variations ..... 90
3.9 Quarters outside FRCE target level 1 and level 2 ..... 94
3.9.1 FRCE Ranges ..... 94
3.9.2 Number of time intervals outside Level 1 and Level 2 FRCE Range ..... 98
3.10 Frequency step around the hour shift ..... 100
Chapter 4. Frequency disturbances exceeding $\mathbf{3 0 0} \mathbf{~ m H z}$ frequency deviation ..... 104
Chapter 5. Summary ..... 131
Chapter 6. Sources ..... 132

## Chapter 1. Introduction

This report presents results of frequency quality study of the Nordic synchronous system for the year 2016. The results have been obtained by analyzing data from Fingrid's PMU (Phasor Measurement Unit) measurements. All times are given in Finnish time (CET+1).

Chapter 2 presents information about the measurement data used in this report. Chapter 3 of the report includes a frequency quality reporting framework proposed by FQ2 (Frequency Quality, phase 2) Project Report. This chapter also presents the frequency quality evaluation criteria defined in the System Operation Guideline (SO GL) as well as results from Fingrid's previous years' frequency quality analysis. The fourth chapter presents in detail frequency disturbances, where the deviation exceeds 300 mHz . The last chapter is a summary of the results.

The term standard frequency range is used to refer to frequencies between 49.9 Hz and 50.1 Hz . Current Nordic target level for number of minutes outside this range is 10000 minutes. 60 second oscillation, which is analyzed in Chapter 3.8, refers to low frequency oscillation observed in the Nordic power system with a time period of roughly 60 seconds.

## Chapter 2. Measurement data

Frequency data for the analysis outlined in this report was gathered from several PMUs at different locations. For every hour, measurements from PMU with the most amount of available data was used. It is assumed that these measurement values represent frequency of the whole Nordic synchronous system. The frequency data used has a sample rate of 10 Hz meaning that the interval between two samples is 0.1 s . The data used in this study can be accessed at Fingrid's website [1].

The amount of valid measurement data in percentages per month in 2016 is presented in Table 2.1. Availability of data per year for years 2011 to 2016 can be seen in Table 2.2 [2,3,4,5,6]. In 2016 there were valid measurement data for $99.37 \%$ of the time. Some of the data is missing due to telecommunication errors. There were two gaps in the measurement data caused by these errors, which lasted more than half an hour. Both of them took place in June, which was clearly the worst month when it comes to the availability of the data.

Table 2.1. The amount of valid measurement data available per month in 2016

| Month | Available data |
| :--- | :--- |
| January | $99.90 \%$ |
| February | $99.89 \%$ |
| March | $99.84 \%$ |
| April | $99.98 \%$ |
| May | $99.96 \%$ |
| June | $93.31 \%$ |
| July | $99.96 \%$ |
| August | $99.97 \%$ |
| September | $99.99 \%$ |
| October | $99.86 \%$ |
| November | $99.90 \%$ |
| December | $99.84 \%$ |

Table 2.2. The amount of valid measurement data available for years 2011-2016

| Year | Available data |
| :--- | :--- |
| 2011 | $95.36 \%$ |
| 2012 | $99.78 \%$ |
| 2013 | $92.14 \%$ |
| 2014 | $99.89 \%$ |
| 2015 | $99.91 \%$ |
| 2016 | $99.37 \%$ |

## Chapter 3. Frequency Quality Indices

This chapter includes frequency quality indices defined and proposed by Frequency Quality, phase 2 Project Report for monitoring frequency quality at all times [7]. Frequency evaluation criteria defined in SO GL (System Operation Guideline) Article 131 are also presented in this chapter. The Article 131 is shown in the following page.

All input frequency data used to calculate the frequency indices is either 0.1 seconds or averages of the 0.1 second data. For example, a resolution of 1 second means that the average of ten 0.1 second values have been used. Most of the proposed indices are presented as averages for every month of the year, day of the week, hour of the day and minute of the hour. In some instances, yearly variation is also included.

System Operation Guideline, Article 131:
"1. The frequency quality evaluation criteria shall comprise:
(a) for the synchronous area during operation in normal state or alert state as determined by Article 18(1) and (2), on a monthly basis, for the instantaneous frequency data:
(i) the mean value;
(ii) the standard deviation;
(iii) the 1- 5 - 5 , 10-, 90- 95 - and 99-percentile;
(iv) the total time in which the absolute value of the instantaneous frequency deviation was larger than the standard frequency deviation, distinguishing between negative and positive instantaneous frequency deviations;
(v) the total time in which the absolute value of the instantaneous frequency deviation was larger than the maximum instantaneous frequency deviation, distinguishing between negative and positive instantaneous frequency deviations;
(vi) the number of events in which the absolute value of the instantaneous frequency deviation of the synchronous area exceeded $200 \%$ of the standard frequency deviation and the instantaneous frequency deviation was not returned to $50 \%$ of the standard frequency deviation for the CE synchronous area and to the frequency restoration range for the GB, IE/NI and Nordic synchronous areas, within the time to restore frequency. The data shall distinguish between negative and positive frequency deviations;
(b) for each LFC block of the CE or Nordic synchronous areas during operation in normal state or alert state in accordance with Article 18(1) and (2), on a monthly basis:
(i) for a data-set containing the average values of the FRCE of the LFC block for time intervals equal to the time to restore frequency:

- the mean value;
- the standard deviation;
- the 1-,5-, 10-, 90-,95- and 99-percentile;
- the number of time intervals in which the average value of the FRCE was outside the Level 1 FRCE range, distinguishing between negative and positive FRCE; and
- the number of time intervals in which the average value of the FRCE was outside the Level 2 FRCE range, distinguishing between negative and positive FRCE."

### 3.1 Average frequency and standard deviation

This section includes results for average frequency and standard deviation. Chapter 3.1.3 has the combined results for mean value and standard deviation according to SO GL Article 131(a) (i) and 131(b) (i) (1 and 2).

### 3.1.1 Average frequency

The following figures show the average frequency for the year 2016. The resolution of the frequency data that has been used is 1 second. The average frequency is calculated with the following formula, where $f_{i}$ is the value of the frequency and $n$ is the number of samples.
$\bar{f}=\frac{\sum_{i}^{n} f_{i}}{n}$

Figure 3.1 represents the average frequency for every month. Average frequency has been very close to 50 Hz , as even for the worst month in March, the average has been less than 1 mHz from 50 Hz .

Figure 3.1. Average frequency for each month in 2016

Figure 3.2 represents the average frequencies for every day of the week. On average, the frequency has been lower on the weekends and the highest on Mondays.

Figure 3.2. Average frequency for each day of the week in 2016

Figure 3.3 shows the average frequencies during each hour of the day. Frequency is generally lower during the night in hours from 2 a.m. to 5 a.m. The frequency is at its highest during the evenings and around midnight.

Figure 3.3. Average frequency for each hour of the day in 2016

Figure 3.4 shows the average frequency inside the hour. In general the frequency is higher in the latter part of the hour. The difference between consecutive minutes is mostly between 2-4 mHz

Figure 3.4. Average frequency for each minute of the hour in 2016

### 3.1.2 Standard deviation

This section includes the figures representing the standard deviation of frequency during the year 2016. The resolution of the frequency data is 1 second. Below is the formula that was used to calculate the standard deviation.
$\sigma=\sqrt{\frac{1}{n} \sum_{i}^{n}\left(f_{i}-\bar{f}\right)^{2}}$
Figure 3.5 shows the standard deviation for each month in 2016. The lower standard deviation in November and December indicates that the 1 second values were in average closer to 50 Hz during those months. In April and May the standard deviation was slightly higher than during other months.

Figure 3.5. Standard deviation of the frequency for every month in 2016

Figure 3.6 represents the standard deviation for every day of the week. Based on standard deviation, the quality of the frequency improves slightly each day from the start of the week to the end except for Wednesdays when the standard deviation is at its highest.

Figure 3.6. Standard deviation of the frequency for every day of the week in 2016

Figure 3.7 shows the standard deviation during a day. The standard deviation can vary over 10 mHz from the lowest values during night to the highest points around midnight and in the morning.

Figure 3.7. Standard deviation of the frequency for every hour of the day in 2016

Figure 3.8 represents the standard deviation inside one hour. The standard deviation is at its highest in the beginning of the hour. From the 10th minute the standard deviation starts to drop until the half hour mark from where it starts to climb up again.

Figure 3.8. Standard deviation of the frequency for every minute of the hour in 2016

Report

### 3.1.3 Mean value and standard deviation

Mean values and standard deviations of the frequency, according to SOGL Article 131(a) i and ii), month by month for years 2011 to 2016 can be found in Table 3.1 and Table 3.2. Same results are also presented in Figure 3.9.

Table 3.1. Mean values and standard deviations for years 2011-2013

|  | 2011 |  |  | 2012 |  | 2013 |  |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- | :---: |
| Month | Mean <br> value <br> $(\mathrm{Hz})$ | Standard <br> deviation <br> $(\mathrm{mHz})$ | Mean <br> value <br> $(\mathrm{Hz})$ | Standard <br> deviation <br> $(\mathrm{mHz})$ | Mean <br> value <br> $(\mathrm{Hz})$ | Standard <br> deviation <br> $(\mathrm{mHz})$ |  |

Figure 3.9. Mean values and standard deviations for years 2011-2016

Mean values and standard deviations for frequency deviations as per Article 131(b) (i) for year 2016 can be found in Table 3.3. Results show how much frequency has deviated from nominal 50 Hz value. Visual representation can be found in Figure 3.10.

Table 3.3. Mean values and standard deviations for year 2016

|  |  |  |
| :--- | :--- | :--- |
| Month | Mean value (mHz) | Standard deviation (mHz) |
| January | -0.091 | 41.7 |
| February | 0.414 | 40.4 |
| March | -0.546 | 40.1 |
| April | 0.210 | 41.2 |
| May | -0.051 | 39.8 |
| June | -0.413 | 35.8 |

| October | -0.146 | 35.0 |
| November | -0.088 | 33.8 |
| December | -0.053 | 35.1 |
| Entire year | -0.028 | 37.9 |

Figure 3.10. Mean values and standard deviations for year 2016

### 3.2 Frequency area

The frequency area is an indicator of how much the frequency is off 50.0 Hz . The approach can be seen in Figure 3.11. The value is presented as a portion of half of the normal frequency area ( $49.9-50.1 \mathrm{~Hz}$ ). For example, if an hourly value is calculated and the frequency has been equal to 49.9 Hz for the whole hour, the value of this index is $100 \%$. The resolution input frequency data used is 0.1 s . Below Figure 3.11 is also the formula for determining the frequency area.

Figure 3.11. Frequency quality index: Frequency area [7]

Frequency area $=\frac{1}{n * 0.1 \mathrm{~Hz}} \sum_{i}^{n}|f(i)-50.0 \mathrm{~Hz}|$

Figure 3.12 represents the average frequency area for every month in 2016. The percentage of the area was considerably smaller later in the year, which indicates that there was less deviation from 50 Hz during those months.

Figure 3.12. The average frequency area for every month in 2016

The frequency area during each day of the week can be seen in Figure 3.13. The percentage was fairly even between the days with the average area being a little bit smaller during weekends.

Figure 3.13. The average frequency area for every day of the week in 2016

Figure 3.14 has the frequency area for every hour during the day. The figure shows that the deviation of the frequency from 50.0 Hz was smaller in the middle of the night and after noon. The area was at its highest in the first and last hour of the day.

Figure 3.14. The average frequency area for every hour inside the day in 2016

Figure 3.15 represents the frequency area within the hour. The percentage of the frequency area was smaller in the middle of the hour while more deviation occured closer the hour shift.

Figure 3.15. The average frequency area for every minute within the hour in 2016

### 3.3 1-, 5-, 10-, 90-, 95-, 99-percentile of frequency

A certain percentile of frequency indicates the frequency below which a given percentage of the samples in the observation period fall. For example, the 1st percentile is the frequency below which $1 \%$ of the samples are found. The same criteria are also defined in SO GL Article 131(a) (iii). The resolution frequency of the data is 1 second.

The 1st, 5th, 10th, 90th, 95th and 99th percentiles were calculated for every month and for the entire year. Tables 3.4-3.9 contain the results from year 2011 to 2016 . All results are summed up in Figure 3.16.

Table 3.4. The 1st, 5th, 10th, 90th, 95th and 99th percentiles for year 2011

Figure 3.16. The 1st, 5th, 10th, 90th, 95th and 99th percentiles for years 2011-2016

More detailed results for the percentiles of 2016 are shown in the next figures. Figure 3.17 is a visual representation of the given percentiles for each month in 2016. There was more deviation in April and May, as the gap between the lower and higher percentiles was wider in those months.

Figure 3.17. The 1st, 5th, 10th, 90th, 95th and 99th percentile of the frequency for every month in 2016

Figure 3.18 shows the percentiles for every day during the week. Percentiles above 50 were slighly lower during weekends while percentiles below 50 were higher, which indicates that the frequency was closer to 50.0 Hz during the weekends.

Figure 3.18. The 1st, 5th, 10th, 90th, 95th and 99th percentile of the frequency for every day of the week in 2016

Figure 3.19 represents the percentiles inside the day. In terms of the 1st, 5th and 10th percentile, the frequencies were lower in the morning from 7 to 10 and afternoon from 16 to 18. For the 90th, 95th and 99th percentile, those hours had the highest frequencies.

Figure 3.19. The 1st, 5th, 10th, 90th, 95th and 99th percentile of the frequency for every hour of the day in 2016

Inside the hour the variation of the percentiles was fairly low. For the 1st, 5th and 10th percentile, the frequency was lower in the first minutes of the hour. For the other percentiles, the minutes around the hour shift were slighly higher than the ones in the middle of the hour.

Figure 3.20. The 1st, 5th, 10th, 90th, 95th and 99th percentile of the frequency for every minute inside the hour in 2016

The 1st, 5th, 10th, 90th, 95th and 99th percentiles according to SO GL Article 131(b) i(3) are presented in Table 3.10. Figure 3.21 below the table shows results in graphical form. Results are deviations from nominal 50 Hz value.

Table 3.10. The 1st, 5th, 10th, 90th, 95th and 99th percentiles for year 2016

Figure 3.21. The 1st, 5th, 10th, 90th, 95th and 99th percentiles for year 2016

### 3.4 Time outside different ranges

Time outside specific range is calculated by multiplying the number of samples that are outside the given frequency range by the time duration of the sample. This calculation uses data, where the interval between consecutive samples is 1 second.

### 3.4.1 Time outside $49.9-50.1 \mathrm{~Hz}$

Figure 3.22 shows cumulative minutes outside the standard frequency range in 2016. The curves are fairly linear throughout the year. The frequency has been outside the standard range just over 14000 minutes, 7500 min over 50.1 Hz and 6500 min under 49.9 Hz .

Figure 3.22. Cumulative minutes outside the standard frequency range in 2016

Figure 3.23 represents the daily average number of minutes per year that the frequency was outside the standard frequency range. After a decreasing trend after 2011, the duration that the frequency was outside the standard frequency range peaked in 2016.

Figure 3.23. Daily average number of minutes per year that the frequency was outside the standard frequency range in 2011-2016

Same results can be seen in Table 3.11 as percentage of time in and outside the standard frequency range. The availability of data has been taken into account: $100 \%$ corresponds to total time for which data was available.

Table 3.11. Percentage of time over, below and inside the standard frequency range

| Year | $>50.1 \mathrm{~Hz}$ | $<\mathbf{4 9 . 9 ~ H z}$ | $49.9 \mathrm{~Hz}-50.1 \mathrm{~Hz}$ |
| :--- | :--- | :--- | :--- |
| 2011 | $1.38 \%$ | $1.04 \%$ | $97.58 \%$ |
| 2012 | $1.30 \%$ | $0.93 \%$ | $97.76 \%$ |
| 2013 | $1.25 \%$ | $0.97 \%$ | $97.78 \%$ |
| 2014 | $1.07 \%$ | $0.92 \%$ | $98.01 \%$ |
| 2015 | $1.09 \%$ | $0.96 \%$ | $97.96 \%$ |
| 2016 | $1.44 \%$ | $1.25 \%$ | $97.31 \%$ |

Table 3.12 presents total duration in minutes per year that frequency has been over or below the standard frequency range and total of these. Values have been scaled with the availability of data to estimate true minutes per year outside the standard frequency range.

Table 3.12. Minutes over and below the standard frequency range

| Year | $>50.1 \mathrm{~Hz}(\mathrm{~min})$ | $<49.9 \mathrm{~Hz}(\mathrm{~min})$ | Total (min) |
| :--- | :--- | :--- | :--- |
| 2011 | 7258 | 5448 | 12706 |
| 2012 | 6874 | 4916 | 11790 |
| 2013 | 6576 | 5081 | 11657 |
| 2014 | 5608 | 4835 | 10443 |
| 2015 | 5704 | 5049 | 10753 |
| 2016 | 7491 | 6492 | 13984 |

Tables 3.13 and 3.14 contain the total time (in minutes) in which the frequency was outside the standard frequency range (49.9-50.1 Hz) month by month for years 2011 to 2016. These results are based on the evaluation criteria defined in SO GL Article 131(a) (iv). The results from previous tables are not entirely comparable due to differences in availability of measurement data. The same information is presented visually in Figure 3.24.

Table 3.13. Total time in which the frequency was outside the 49.9-50.1 Hz band in years 2011-2013

Figure 3.24. Total time in which the frequency was outside the 49.9-50.1 band in years 2011-2016

Figure 3.25 shows the daily average in minutes month by month when frequency was outside the standard frequency range in years 2011-2016. In 2016, April and May were the months with the longest time outside the standard frequency range. October and November had the best frequency in this comparison.

Figure 3.25. Daily average time that the frequency was outside the standard frequency range month by month for years 2011-2016

Figure 3.26 represents the daily averge time that the frequency was outside the standard frequency range during each day of the week. Year 2016 was one of the worst years in this relation. Every year has had a similar pattern, where the frequency has been outside the standard frequency range more often during weekdays than weekends.

Figure 3.26. Daily average time that the frequency was outside the standard frequency range during each day of the week for years 2011-2016

## FINGRID

Figure 3.27 represents the daily average time that the frequency was outside the standard frequency range for each hour in the day. The hours are according to the Finnish time (UTC+2 / UTC+3 in the summer). The highest over frequency deviations in 2016 were at the hours 23 and 0 and under frequency deviations at 1 and 7 . The worst frequencies in previous years in this case have also been at the morning hours and in the evening and midnight. Frequency has stayed inside the standard frequency range for the most at the hours from 3 to 5 . Hours from 12 to 15 have also been rather good.

Figure 3.27. Daily average time that the frequency was outside the standard frequency range during each hour of the day for years 2011-2016

Figure 3.28 shows the daily average time outside the standard frequency range per hour and absolute value of Nordic consumption and production difference. Also transmission difference of HVDC links connecting Nordic power system to Continental Europe and Russia is presented.

The differences were calculated by subtracting average power of the previous hour from the corresponding value of the current hour. Consumption and production data was retrieved from the Nord Pool website and the powers of the HVDC links were direct measurement data. Hours are given in Finnish time (UTC+2 / UTC+3 in the summer).

The Nordic production difference curve peaks at nearly 4000 MWh while the consumption difference curve peaks close to 2500 MWh in the morning hours 7 and 8 . Near midnight the peaks are around 2000-2500 MWh. Highest values of frequency deviations are also found during these hours. Differences in HVDC transmission does not peak as high but the curve still follows the same pattern as production and consumption difference. Results for year 2015 were very similar to the year 2016 [6].

Figure 3.28. Seconds per hour outside the standard frequency range and the absolute values of Nordic consumption, production and HVDC transmission differences in 2016

Figure 3.29 illustrates an average hour divided to 60 minutes. For each minute of the average hour there is a value in seconds per hour that frequency has been over or below the standard frequency range. In years 2011-2016 frequency has been outside the standard frequency range more often during beginning of hours. Frequency has stayed best inside the standard frequency range in the middle of hours. The amount of over frequency deviations have increased again towards the end of hours.

Figure 3.29. Number of seconds per hour outside the standard frequency range in 2011-2016 for each minute of an average hour

Figure 3.30 illustrates an average minute divided to 60 seconds. For each second of the average minute there is a value in milliseconds per minute that frequency has been over or below the standard frequency range. Shape of the curve is fairly smooth so there hasn't been large deviations inside one minute. There have been slightly more over frequencies at the beginning and at the end of minutes. Under frequencies have occurred more at the middle of minutes. In 2016 the number of milliseconds per minute under the standard frequency range has been considerably higher than in previous years.

Figure 3.30. Number of milliseconds per minute outside the standard frequency range in 2011-2016 for each second of an average minute

### 3.4.2 Time outside $49.8-50.2 \mathrm{~Hz}$

Figure 3.31 shows frequency deviations exceeding $\pm 200 \mathrm{mHz}$ as average number of seconds per day. The amount of these deviations was higher in 2016 than during any previous years. In 2011 and 2012, average number of seconds over 50.2 Hz was considerably more than under 49.8 Hz while in 2013, it was the other way around. For the last three years, there has been only slight difference between over and under frequencies.

Figure 3.31. Average number of seconds per day that the frequency was outside the 49.8-50.2 Hz band for years 2011-2016

Public

The number of events for which the frequency deviation exceeded $\pm 200 \mathrm{mHz}$ and did not return to the standard frequency range within the next 15 minutes has been calculated using two different methods. The number of events are also specified in Article 131 (1a vi).
Method 1: the number of events for which the frequency deviation exceeded $\pm 200 \mathrm{mHz}$ and none of the frequency samples were inside the standard frequency range within the next 15 min Method 2: the number of events for which the frequency deviation exceeded $\pm 200 \mathrm{mHz}$ and the 120 second moving average did not return to the standard frequency range within the next 15 min . The 120 second period was chosen because it is not significantly affected by the natural 60 second oscillation of the frequency and thus it was considered suitable for determining if the frequency restoration was permanent.

Figure 3.32 shows a frequency deviation from December 2016. The deviation starts at 0 s as the frequency exceeds 50.2 Hz and the figure shows the following 15 minutes. This deviation is not counted as an event when using method 1 , because the frequency goes momentarily inside the standard frequency range around 750 seconds from the start. By using method 2, this deviation is counted as an event. The 120 second moving average does not go inside the standard frequency range at any point during the 15 minute period. The used resolution of the frequency data was 1 second.

Figure 3.32. Comparison of methods for calculating the number of events, where df > 200 mHz and not restored within 15 min

The number of events in 2011-2016 that the frequency exceeded 49.8-50.2 Hz band and did not even momentarily return to the standard frequency range within 15 minutes are presented in Table 3.15. These results were calculated with method 1.

Table 3.15. Number of events for which the frequency deviation exceeded $\pm 200 \mathrm{mHz}$ and the frequency did not return to the 49.9-50.1 Hz band within 15 minutes. Calculated with method 1.

### 3.4.3 Time outside $49.0-51.0 \mathrm{~Hz}$

Time outside 49.0 Hz and 51.0 Hz is calculated by counting the number of samples that are below 49.0 Hz or above 51.0 Hz and multiplying the number by the time duration of the sample. The criteria are also defined in SO GL Article 131(a) (v). The resolution of the data used was 1 second.

There were no instances in 2011-2016 where the frequency crossed 49.0 Hz or 51.0 Hz .

### 3.5 Number of frequency deviations with different durations

In this section, the frequencies outside the standard frequency range have been sorted according to amplitude and duration of the deviation, as well as whether the deviation was over or under the normal frequency range. Figure 3.33 gives an example on how the frequency deviations have been calculated. The example situation has two frequency deviations with different durations going below 49.900 Hz . This time period increases the number of frequency deviations < 49.900 Hz by two (2): one addition to $10-20 \mathrm{~s}$ column and one to $5-10 \mathrm{~s}$ column. The other frequency deviation goes also below 49.800 Hz and 49.700 Hz . These will also be counted as one frequency deviation $<49.800 \mathrm{~Hz}$ with time from $5-10 \mathrm{~s}$ and one $<49.700 \mathrm{~Hz}$ with time from 1-5 s. Altogether, this time is counted as four (4) frequency deviations. Also for example, time window of $5-10$ s stands for frequency deviations lasting over five (5) seconds and under or exactly 10 seconds.

Figure 3.33. Example on how the number of frequency deviations is calculated [6]

### 3.5.1 Deviations with a duration of 0-1 s, 1-5 s, 5-10 s, 10-20 s, 20-40 s, 40-60 s and

 1-3 minThe resolution of the frequency data that was used is 0.1 seconds.
Tables 3.17-3.22 provide more detailed information about frequency deviations from year 2011 to 2016. These tables include the durations and amplitudes of the deviations, as well as total amount, maximum duration and average duration of deviations.

Figure 3.34 is a visual representation of the data in Tables 3.17-3.22. Number of deviations are now given as a daily average instead of total amount per year. There was a remarkable fall in the number of short-lasting frequency deviations from year 2013 to 2014. The amount of shortlasting deviations rose once again from 2014 to 2016.

Figure 3.34. Daily average number of frequency deviations per duration

Table 3.23 shows how deviations of different duration affected to the total time outside the standard frequency range in 2016. Times are given in minutes. Pie chart in Figure 3.35 shows in percentages how the total time outside the standard frequency range was divided between deviations of different duration. Deviations with duration of 10-20 s and 20-40 s lasted almost half of the total time outside the standard frequency range.

Table 3.23. Total minutes in 2016 that the frequency was outside the standard frequency range per duration of deviations

|  | $\mathbf{0 - 1} \mathbf{s}$ | $\mathbf{1 - 5} \mathbf{s}$ | $\mathbf{5 - 1 0}$ <br> $\mathbf{s}$ | $\mathbf{1 0 - 2 0}$ <br> $\mathbf{s}$ | $\mathbf{2 0 - 4 0}$ <br> $\mathbf{s}$ | $\mathbf{4 0 - 6 0}$ <br> $\mathbf{s}$ | $\mathbf{1 - 3} \mathbf{~ m i n}$ | $>\mathbf{3} \mathbf{~ m i n}$ | total |

Figure 3.35. Percentage of total time outside the standard frequency range caused by deviations of different durations

The following figures go into more detail on the deviations in the year 2016. Figure 3.36 represents the total number of devations per duration for each mont in 2016. Most of the deviations lasted only $0-1$ seconds. April and May had the most frequency deviations across all durations. The least amount of devitions occurred in November and December.

Figure 3.36. Total number of frequency deviations per duration for each month in 2016

Figure 3.37 shows the number of deviations for every day of the week. Deviations under 49.9 Hz were all quite even across all days but most of the deviations over 50.1 Hz took place in the beginning of the week on Monday, Tuesday and Wednesday.

Figure 3.37. Total number of frequency deviations per duration for each day of the week in 2016

Figures 3.38 and 3.39 illustrate the number of deviations per duration inside the day with Figure 3.38 including hours from 0-11 and Figure 3.39 the hours from 12-23. By far most of the deviations over the standard frequency range were around midnight on the first and last hours of the day.

Figure 3.38. Total number of frequency deviations per duration for hours 0-11 in 2016

Figure 3.39. Total number of frequency deviations per duration for hours 12-23 in 2016

Figure 3.40 represents duration curve of maximum frequency deviation inside different time windows in year 2016. The time window was slid through the year with a time interval of one second. Studied time windows can be found from legend of the Figure 3.40. Chapter 4 shows in detail frequency disturbances of over 0.3 Hz which can be seen here as a peak near 100\% permanence.

Figure 3.40. Duration curve of maximum frequency deviation inside different time windows in 2016

### 3.5.2 Deviations with a duration of 1-3 $\mathbf{~ m i n}, 3-5 \mathrm{~min}, 5-10 \mathrm{~min}, 10-15 \mathrm{~min}$ and $>15$ min

The resolution of the frequency data used for these durations is one minute and only results for 2016 are presented. Figure 3.41 shows the total number of deviations for each month in 2016. The first half of the year had generally more longer lasting durations than the latter part of the year.

Figure 3.41. Total number of longer frequency deviations per duration for each month in 2016

Figure 3.42 represents the number of deviations with different durations during every day of the week in 2016. From Monday to Thursday with 1-3 min durations, the total number of deviations is fairly even. During Monday and Tuesday, most of the deviations were over 50.1 Hz and for Wednesday and Thursday, the deviations were more often under 49.9 Hz . Especially during the weekends, there were less deviations.

Figure 3.42. Total number of longer frequency deviations per duration for each day of the week in 2016

Figures 3.43 and 3.44 follow the same pattern as the figures representing the shorter durations with most deviations taking place around midnight, in the morning and during evening hours.

Figure 3.43. Total number of longer frequency deviations per duration for hours 0-11 in 2016

Figure 3.44. Total number of longer frequency deviations per duration for hours 12-23 in 2016

### 3.6 Number of threshold crossings

The number of threshold crossings is calculated by counting the number of samples for which the frequency is outside the standard frequency range and the previous sample is inside the range. The number of threshold crossings is a good indicator on how many times per given time period FCR-D is activated. The crossings are calculated separately for the number of occasions the frequency goes over and under the frequneycy range. The resolution of the frequency is one second.

### 3.6.1 Number of 49.9-50.1 Hz crossings

Figure 3.45 shows the daily average numbers of over and under frequency deviations from 2011 to 2016. The amount has remained fairly even from 2012 to 2015, but increased in 2016. Every year there has been slightly more threshold crossings over 50.1 Hz than under 49.9 Hz .

Figure 3.45. Daily average number of frequency deviations for years 2011-2016

Figure 3.46 represents the daily average number of threshold crossings for each month in 2016. There has been slightly more crossings over 50.1 Hz than crossings under 49.9 Hz . In total, the frequency crossed the threshold more often during spring and summer months.

Figure 3.46. Daily average number of threshold crossings for every month in 2016

Figure 3.47 shows the number of threshold crossings for each day of the week in 2016. During the weekends, the number was smaller and more crossings were under 49.9 Hz than over 50.1 Hz .

Figure 3.47. Daily average number of threshold crossings for every day of the week in 2016

The number of threshold crossings inside the day on average is in Figure 3.48. Not surprisingly, the least amount of threshold crossings occur in the night from 2 to 4 and afternoon from 11 to 16. Close to midnight and in the morning around 7 is when the frequency crosses the threshold more often.

Figure 3.48. Average number of threshold crossings for every hour of the day in 2016

Figure 3.49 represents the average number of threshold crossings for every minute inside the hour. Most crossings take place within the first minutes of the hour. During the first 30 minutes of the hour, the frequency crosses 49.9 Hz more often, while more crossings of 50.1 Hz take place in the latter part of the hour.

Figure 3.49. Average number of threshold crossings for every minute of the hour in 2016

### 3.6.2 Number of $49.8-50.2 \mathrm{~Hz}$ crossings

Figure 3.50 represents the average number of frequency deviations per day that exceeded $\pm 200$ mHz . The number is significantly higher in 2016 than in 2011-2015.

Figure 3.50. Daily average number of frequency deviations larger than $\pm 200 \mathbf{m H z}$ for years 2008-2016

### 3.7 Length of frequency path

The length of the path that frequency takes shows how much the frequency travels around the 50.0 Hz , as can be seen from Figure 3.51. The length of the path is calculated per time period and the length of the time step is taken into account. The resolution of the frequency data used is 0.1 seconds. Under Figure 3.51 is the formula for frequency path, where $\Delta t$ is the length of the time step (in this case 0.1 s ).

Figure 3.51. Frequency quality index: Length of the frequency path [7]

Frequency path $=\left(\frac{\sum_{i}^{n} \sqrt{(f(i)-f(i-1))^{2}+\Delta t^{2}}}{(n-1) * \Delta t}\right)-1$

Figure 3.52 represents the frequency path for each month in 2016. On average, the path has been longer in the middle of the year from April to September.

Figure 3.52. Length of the frequency path month by month in 2016

The frequency path for every day of the week shows in Figure 3.53. There has been little to no variation in frequency path between the days. During weekends the path has been slightly longer on average.

Figure 3.53. Length of the frequency path for every day of the week in 2016

Figure 3.54 shows the frequency path during the day. The path is longer closer to the shift of the day and shorter around noon.

Figure 3.54. Length of the frequency path for every hour of the day in 2016

Figure 3.55 represents the average frequency path for every minute inside the hour. The path is longer during the first minutes of the hour, but otherwise it stays pretty even throughout the hour.

Figure 3.55. Length of the frequency path for every minute of the hour in 2016

### 3.8 Amount of frequency oscillation

Frequency of the Nordic synchronous system oscillates constantly. Time period of the oscillation is approximately 40 to 90 seconds. This behavior is a natural characteristic of the system but it can be influenced through adequate settings of system reserves. Oscillation has an increasing effect on the time outside the standard frequency range. It also causes wear of reserve machines when controller settings are not optimal for the machine.

### 3.8.1 Methodology

The 60 second oscillation was studied using Fourier transform which can be used to decompose time series signals such as frequency measurements into sinusoidal frequency components. In other words, sum of these sinusoidal components forms the original signal. Each of the frequency components has an amplitude and a phase. The amplitude of a certain frequency component represents the amount of sinusoidal oscillation at that frequency. It is possible to modify the signal in the frequency domain and then construct time domain representation of the modified signal. [8]

The method used is such that the desired frequency band is filtered from the frequency data in order to estimate what the frequency would look like without the oscillation. It is possible to filter desired frequency components only partially or entirely remove them. In this study, as well as in reports from previous years $[6,8,9]$, the frequency components were removed. Area between the filtered frequency signal and the original signal is used to represent the amount of oscillation. The approach is shown in Figure 3.56 [8].

Figure 3.56. Frequency quality index: Amount of frequency oscillation [7]

Filtering band used in all studies was 30-240 s. Choice is based on comparison between different bands in the 2011 and 2012 oscillation analysis [8] . Frequency spectrum calculated from a sample containing the first 20 minutes of December 2012 is shown in Figure 3.57. Frequency bands corresponding to the 40-90 s and 30-240 s bands are marked on the figure. Figure 3.58 is an estimation of the frequency when these bands are filtered. In the studies, Fourier transform was calculated for time intervals of one hour. The actually used band is 30225 s and due to the nature of FFT it might vary slightly depending on the length of the data sample.

For the FFT-filtering calculation there were two requirements for the data: there had to be at least $90 \%$ of eligible data for each hour and measurement frequency had to stay at least at 4 Hz . If these requirements were not fulfilled that hour was skipped and removed from the calculations.

Figure 3.57. Frequency spectrum representing first 20 minutes of December 2012 (UTC+2). Green line corresponds to 40-90 s band and red line corresponds to 30-240 s band [8]

Figure 3.58. Original frequency (blue), frequency with 40-90 s band filtered (green) and frequency with 30-240 s band filtered (red). First 20 minutes of December 2012 are shown (UTC+2) [8]

### 3.8.2 Amount of oscillation

Figure 3.59 shows hourly values and 24 hour moving averages for the amount of oscillation in 2016. The 24 hour moving averages were calculated if there was enough eligible data for at least 12 hours in the frame of 24 hours.

Gaps in the following curves indicate that there were not enough eligible data for the calculations.

The 24 h moving average is at its highest in the summer and autumn. There is a slight drop in oscillation at the end of July. January had the least amount of oscillation in 2016.

Figures 3.60 and 3.61 contain the previously mentioned 24 hour moving averages for years 2011-2013 and 2014-2016, respectively. In the calculations for years 2011-2015 it was required that there had to be enough eligible data for at least 22 hours in the frame of 24 hours.

Figure 3.59. Amount of oscillation in 2016

Figure 3.60. Amount of oscillation in 2011-2013

Figure 3.61. Amount of oscillation in 2014-2016

Mean value of the oscillation and standard deviation for each month from 2011 to 2016 are shown in Table 3.24 and 3.25. Figure 3.62 represents the same information in a visual form. In year 2016 frequency has oscillated the most between May and September. Frequency oscillated more in 2016 than in previous year 2015. Year 2016 has been among the worst years in terms of oscillation.

Table 3.24. Mean values and standard deviations for oscillation in years 2011-2013

|  | Mean value (Hzs) |  |  | Standard deviation (Hzs) |  |  |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- |
| Month | $\mathbf{2 0 1 1}$ | $\mathbf{2 0 1 2}$ | $\mathbf{2 0 1 3}$ | $\mathbf{2 0 1 1}$ | $\mathbf{2 0 1 2}$ | $\mathbf{2 0 1 3}$ |
| January | 43.5 | 42.1 | 43.8 | 4.3 | 4.5 | 5.3 |

Figure 3.62. Mean values (left y-axis) and standard deviations (right y-axis) for oscillation in years 2011-2016

### 3.8.3 Influence of oscillation on frequency variations

Aim of this section is to analyze to what extent the deviations from the standard frequency range have been caused by the 60 second oscillation of the frequency.

Figure 3.63 shows the average minutes per day outside the standard frequency range in 2016 without filtering and after applying FFT-filtering. Figure 3.63 shows the average only for minutes per day outside the standard frequency range that had enough consecutive samples for one hour periods for the FFT-algorithm.

Figure 3.63. Average time per day outside the standard frequency range in 2016

In Figure 3.64, the reduction of time outside the standard frequency range through filtering is presented as percentages of the original values. The results show that filtering leads to significant reduction in time outside the standard frequency range.

Figure 3.64. Reduction in time per month outside the standard frequency range after filtering in 2016

Figure 3.65 represents the reduction in time outside the standard frequency range in percentages month by month for years 2011 to 2016.

Figure 3.65. Reduction in time per month outside the standard frequency range after filtering in years 20112016

In addition to the monthly values presented in the previous figure, results for the entire year in 2011-2016 are shown below in Figure 3.66.

Filtering the oscillation reduces duration of frequency deviations around 35-40 \%. The reduction has been roughly on the same level from year to year. The reduction is about $10 \%$ more for under frequency deviations.

Figure 3.66. Reduction in time outside the standard frequency range after filtering for years 2011-2016

### 3.9 Quarters outside FRCE target level 1 and level 2

### 3.9.1 FRCE Ranges

The FRCE Ranges have been calculated according to the SO GL Article 128, which is presented below.

System Operation Guideline, Article 128:
"3. All TSOs of the CE and Nordic synchronous areas shall endeavour to comply with the following FRCE target parameters for each LFC block of the synchronous area:
(a) the number of time intervals per year outside the Level 1 FRCE range within a time interval equal to the time to restore frequency shall be less than $30 \%$ of the time intervals of the year; and
(b) the number of time intervals per year outside the Level 2 FRCE range within a time interval equal to the time to restore frequency shall be less than $5 \%$ of the time intervals of the year."

FRCE Ranges were calculated by calculating mean values of 15 -minute moving averages. This method was used as it is thought to result in descriptive results. Time intervals with corrupted measurements were disregarded. The frequency data that used in the calculation has a time interval of 100 ms between two consecutive samples.

Table 3.26 and 3.27 show the FRCE Ranges for years 2011-2016. The same results are presented in a graphical form in Figure 3.67

Table 3.26. FRCE Ranges for NE, calculated with 15 min moving averages, years 2011-2013

Figure 3.67. FRCE Ranges for years 2011-2016 calculated with 15 min moving averages

### 3.9.2 Number of time intervals outside Level 1 and Level 2 FRCE Range

Table 3.28 shows the number of 15 minute time intervals over Level 1 and Level 2 FRCE Ranges in year 2016. This evaluation criteria is defined in Article 131(b) i(4 and 5). Because the ranges were calculated by sliding the 15 minute interval through the whole year the same principle was used here also. To keep the amount of 15 minute time intervals the same as if they were searched categorically from the beginning of the year (as SO GL might suggest), the already found crossing and the next 15 minutes from it were removed from the next calculations. Figure 3.68 gives a visual representation of the results in Table 3.28.

Table 3.28. The number of 15-minute time intervals over positive and under negative Level 1 and Level 2 FRCE Ranges month by month in 2016

|  | 2016 |  |  |  |  |  |
| :--- | :--- | :--- | :--- | :--- | :---: | :---: |
| Month | Level 1 (+) | $<$ Level 1 (-) | $>$ Level 2 (+) | < Level 2 (-) |  |  |
| January | 460 | 469 | 92 | 61 |  |  |

Figure 3.68. The number of time intervals over positive and under negative FRCE Level 1 and Level 2 Ranges for year 2016

### 3.10 Frequency step around the hour shift

The frequency step around the hour shift is defined by the difference between the highest and the lowest frequency during the period from 5 minutes before to 5 minutes after the hour shift. A negative sign is added if the highest frequency takes place before the lowest frequency. The frequency step is calculated for every hour shift in 2016. Of the total samples in a period, the 1st, 5th, 10th, 50th, 90th, 95th and 99th percentile are determined. Figure 3.69 shows the definition of deterministic frequency deviation. The resolution of the frequency data was 1 second.

Figure 3.69. Definition of deterministic frequency deviation [7]

Figure 3.70 represents the deterministic frequency deviation per month in 2016. The 50th percentile stays below zero for the entire year, which indicates that the highest frequency took place before the lowest in more than half of the hour shifts.

Figure 3.70. The 1st, 5th, 10th, 50th, 90th, 95th, and 99th percentile of deterministic frequency deviation for every month in 2016

Figure 3.71 shows the percentiles around the hour shift for every day of the week in 2016. The 1 st, 5 th, 10 th and 50 th percentile are all a touch higher during the weekends.

Figure 3.71. The 1st, 5th, 10th, 50th, 90th, 95th, and 99th percentile of deterministic frequency deviation for every day of the week in 2016

The percentiles of the frequency step around the hour shift for each hour of the day have more variety than the previous figures, as can be seen from Figure 3.72. During morning hours from 5 to 10 and in the evening from 17 to 19, the value for the 50th percentile was positive, which means the lowest frequency took place before the highest in more than half of the hour shifts during those hours.

Figure 3.72. The 1st, 5th, 10th, 50th, 90th, 95th, and 99th percentile of deterministic frequency deviation for every hour of the day in 2016

## Chapter 4. Frequency disturbances exceeding 300 mHz frequency deviation

This chapter offers information of the major frequency disturbances in the Nordic synchronous system in the year 2016. Over 300 mHz frequency deviations are included.

Measurement data used for this study is from Fingrid's PMU located in Espoo. Measurement frequency for the PMU was 10 Hz . This data describes at a fair accuracy frequency of the whole Nordic system.

Most of over $\pm 300 \mathrm{mHz}$ disturbances were caused by failures in HVDC links, which can be seen from Figure 4.1. The second most common cause for disturbances were failures in nuclear power production.

Figure 4.1. Shares of factors causing over 300 mHz disturbances in the Nordic synchronous system in 2016

Most failures in HVDC links caused over frequencies of 50.25 Hz and above. Drops of nuclear plants naturally led to under frequencies with an amplitude from 49.8 Hz to 49.6 Hz . Rest of the disturbances were caused by faults in AC-lines and industry, which led to under frequencies.

The largest maximum frequency deviation was caused by failure in AC-line on the 4th of July with a value of 0.454 Hz . This also caused the lowest instantaneous frequency of 49.553 Hz . The highest instantaneous frequency value was 50.360 Hz caused by the tripping of HVDC link on the 15th of May.

The following part of the chapter will go into more detail on every disturbance that took place in 2016. This will include figures of the frequency when the major disturbances have occurred and information about the disturbance in table form. Table 4.1 contains a short summary of the studied disturbances. Times presented are in the Finnish time (UTC+2 / UTC+3 in the summer). The information given are proposed indices from the FQ2 Project Report and will include:

- date
- $\mathrm{f}_{\text {start }}=$ frequency at the start of the disturbance
- $\mathrm{f}_{\text {extreme }}=$ the minimum or maximum instantaneous frequency
- $\Delta f=$ maximum frequency deviation
- $\Delta t=$ time to reach the maximum frequency deviation
- $\Delta P=$ maximum power deviation
- $\mathrm{E}_{\mathrm{k}}=$ synchronously connected kinetic energy before disturbance
- cause of the disturbance
- $\mathrm{f}_{\text {steady state }}=$ average of the frequency between 90 and 150 s after the disturbance
- $\Delta f_{\text {steady state }}=$ absolute difference between $f_{\text {steady state }}$ and $f_{\text {start }}$
- $\mathrm{f}_{\text {extreme2 }}=$ second extreme in the other direction as $\mathrm{f}_{\text {extreme }}$
- $f_{\text {extreme3 }}=$ third extreme in the same direction as $f_{\text {extreme }}$
- damping of frequency after disturbance $=\left|\left(f_{\text {extreme3 }}-f_{\text {extreme2 }}\right) /\left(f_{\text {extreme2 }}-f_{\text {extreme }}\right)\right|$
- Frequency Bias Factor $(\mathrm{FBF})=\Delta \mathrm{P} / \Delta \mathrm{f}_{\text {steady state }}$

Frequency response indicators mentioned above are visually illustrated in Figure 4.2.

Figure 4.2. Graphical representation of frequency response indicators [11]

Some of the disturbances included have $\Delta f$-values below $300 \mathrm{mHz} . \Delta f$ is defined to be the absolute value between $f_{\text {start }}$ and $f_{\text {extreme }}$ as seen in Figure 4.2. In some cases there was a frequency deviation at a later moment that was higher than $\Delta \mathrm{f}$ and exceeded the $\pm 300 \mathrm{mHz}$ deviation. Those cases were included also. [11]

Kinetic energy $\left(E_{k}\right)$ is an estimation of the rotation energy of synchronously connected generators in the Nordic synchronous system. Values for kinetic energy are given because it affects to the system inertia which describes system's ability to oppose changes in frequency. Higher kinetic energy provides higher inertia and therefore better ability to oppose frequency deviations. [11]

More detailed descriptions of the events listed in Table 4.1 are presented afterwards in Figures 4.3-24 and Tables 4.2-23.

## Chapter 5. Summary

The aim of this report was to analyze frequency variation and oscillation in the Nordic synchronous system in 2016. The overall quality of frequency was worse than in the previous year of 2015 and among the worst of all the years examined in this report.

The average duration of frequency deviations varies on monthly and daily basis. The monthly results vary from year to year but the highest values have often occurred in March to May and August to October. Highest values in 2016 were observed in April and May. November and December had the best quality of all months in 2016. Typically frequency has stayed within the standard frequency range better at weekends than during the weekdays. This was the case in 2016 as well.

Within a day the frequency rises above 50.1 Hz most often around midnight and falls below 49.9 Hz at hours 1,7 and 8 . Generally there are more deviation in the morning and evening hours while the least amount of deviations occur in hours 2-5 and 12-16. Inside an hour the quality of the frequency is worse closer the hour shift and especially at the beginning of the hour.

The amount of oscillation in 2016 was higher than in any previous years from 2011 to 2015. The mean value of oscillation was highest in May and June and the standard deviation in June and July. During the past years the frequency has oscillated less during winter and more from spring to autumn. Year 2016 was not an exception in this case.

Removal of the oscillation by filtering the frequency data clearly reduces frequency deviations. The reduction is about $35-40 \%$ with the FFT-filtering method. The reduction is close to $10 \%$ more for under frequency deviations.

There were 22 frequency disturbances in 2016, where the deviation exceeded 300 mHz . By far the most common reason for the disturbances were failures in HVDC links, as they were the cause for nearly $70 \%$ of the disturbances. The amount of frequency deviations exceeding 300 mHz was very similar in 2015 as well.
